Chapter 1

Introduction

This chapter presents the problem that the project tries to solve and describes the scope of the thesis. It also describes the document structure.

1.1 Introduction into the problem domain

In today's world information technology (IT) is present in almost every aspect of our lives. It is constantly being utilised by governments, military, organisations, financial institutions, universities and other businesses to process and store enormous amounts of data as well as transmit it between many computers around the globe. Any disruption to the work of those systems or unauthorized access to the stored information may result in significant losses. Those may include financial and geopolitical repercussions but also direct losses of human lives in situations where the target of an attack is for example a hospital. Since the inception and propagation of IT the security of the systems in question is growing concern of corporations, countries and even individuals. Because of the constant arms race between adversaries attacking and defending IT systems, anyone who is not proactively handling matters concerning cyber security is instantly falling behind. [14]

A typical attack on an IT system may include exploitation of a design flaw to gain increased access. The offensive actions can target many different layers of abstraction present in current IT systems. Such situations are extremely hard to discover and guard against due to the fact that they were not foreseen in the design

process. How to guard against something that is not known to be possible. There are many approaches that aim to increase the security of IT systems. Some popular ones include fingerprinting malware, monitoring software for specific suspicious actions or monitoring software inputs for known malicious values. Those approaches can be very effective but failures are inevitable.

To mitigate this problem multiple studies have been done that attempt to utilise the methods of anomaly detection known from the data science fields in order to identify the misbehaviours of the monitored IT systems which could allow for an early detection of novel 0-day based intrusions. The past investigations of the problem have focused on analysis of the information obtained from multiple sources like system commands sequences [17] or system calls [15]. There are however still many mechanisms present in modern operating systems that gather significant quantities of information about inner workings of the processes executed on them.

The objective of this thesis is to utilise the Event Trace for Windows (ETW) mechanism and its capability to access low level debugging data on the Microsoft operating systems to attempt security anomaly detection. The main focus is placed on identification of 0-day binary process exploitation leading directly to arbitrary code execution. While taken under consideration in light of gathered information, other attack types like for example DLL hijacking are not in scope of this work.

1.2 Authors contribution

Author of the thesis has simulated a 0-day exploitation attack on a web browser and gathered the data generated in the process via the Event Trace for Windows mechanism. This process required establishing of the information gathering framework. The acquired information was processed to identify and extract features that could be utilised in an anomaly detection methods. This procedure included developing some novel data encoding approaches. Gathered data was tested with known classification algorithms and the results of the experiments were analysed. Based on the performed actions a conclusion was formed about the usefulness of the ETW data in potential anomaly detection based security system. Additionally further research directions have been established.

1.3 Chapters description

This thesis is constructed with following chapters.

- Introduction - Describes the domain of the researched problem and the basis for the topic of the thesis. Highlights the the contributions of the author. Provides overview of the chapters present in this document.
- Problem analysis - Theoretical indepth study of the work required to achive the thesis goal. Investigation of known literature related to the researched topic. Description of the previous known solutions of the problem.
- Security anomaly detection based on Windows Event Trace - Full description of the proposed solutions and their theoretical analysis. Rationalization of the employed algorithms, methods and tools.
- Data gathering - Thorough explanation of the performed data gathering process and of the obtained results.
- Experiments - Full description of all experiments performed in the process of thesis research. Analysis of the outcomes.
- Summary - Synopsis of the performed work. Summary of all the resulting conclusions and possible future research directions. Analysis of the thesis goal in light of the obtained results.

Chapter 2

Problem analysis

This chapter is a indepth overview of the problem related information available in the public litelature and resources. Additionally it contains analysis of complications possibly encountered durring the realisation the required work.

2.1 (

Known problems) There are multiple problems that need to be solved to form conclusions to the stated questions. There are no commonly available security focused datasets sourced from the Event Trace for Windows mechanism. The data used in the thests has to be generated and gathered as part of the performed work. The information processed by the ETW is very broad and can be additionally extended. A analysis has to be done in order to identify the features that can prove useful in the security anomaly detection scenarios.

Gathered data might require preprocessing that will adjust it's form to the formats accepted in the current classification methods and algorithms. Some types of information present in the computer generated data set might require utilisation of novel processing and encoding frameworks or development of new approaches to them.

2.2 Literature research

The previous attempts of implementing a security anomaly detection frameworks depicted in the literature take many different approaches. Some of those include analysis of specific sequences present in terminal commands [17] or system calls [12].

Some researchers attempt to implement novel custom classification methods. An example of such approach is depicted in "An Application of Machine Learning to Anomaly Detection" by Terran Lane and Carla E. Brodley[17]. The authors gather historical sequences of terminal commands and their corresponding utilised command flags. The obtained vectors are utilised to calculate similarity measures with the incoming data. Those values are utilised to identify whether the user interacting with the system was previously profiled by the algorithm. Other approaches classify available data with well known algorithms like various Support Vector Machines (SVM) and K-means like Wenjie Hue, Yihua Liao and V Rao Vemuri in "Robust Support Vector Machines for Anomaly Detection in Computer Security" [15]. Their work compares the performance of Robust Support Vector Machines (RSVM), Support Vector Machines and K-means classifiers on the data from 1998 DARPA Intrusion Detection System Evaluation program. Obtained results prove the superiority of RSVM's in the tested use cases. Some researchers try to perform security data classification with novel anomaly detection methods like autoencoders. This approach was attempted for example in "Anomaly Detection on the Edge" by Joseph Schneible and Alex Lu [21]. This method learns to compress and decompress the available feature vectors with the use of artificial neural vectors. Anomaly is detected when the distance between the input and output of the neural net is higher than the specified threshold.

Chapter 3

Security anomaly detection based on Windows Event Trace

This chapter contains indepth description of the solutions proposed for the thesis problems.

3.1 Data gathering

To achieve the goal of the thesis a dataset based of the Windows Event Trace has to be created. The ETW framework can be accessed and utilised via API available in multiple programing languages like C/C++[5] or C#[4]. The data gathering process should however be performed with known and tested solutions to minimise the chance of data corruption. The default file format used by ETW for storing information is a Event Trace Log (ETL). This archive type is not very well documented in the resources available on the internet. A additional tool might be required in order to transform gathered information to commonly known data storing formats.

Event Trace for Windows handles very granular process and operating system events. Because of that when configured to gather all possible types of information ETW can generate large quantities of information. Additionally known tools gather data in rotating memory buffer before saving it to hard drive. Those two factors combined with limited memory resources available while performing the

data gathering process limit the types of information analysed in the thesis.

Based on the studied literature one of the well-suited result presentation methods is the Receiver Operating Characteristic (ROC) curve which is a plot of the detection accuracy against the false positive ratio. The probability of false anomaly detection is crucial because it may cause overload on of the response teams and mechanisms which in turn may result in delayed response or omission of actual exploitation.

3.2 Analysed data

Available information has been narrowed down to following features analysed to achieve the thesis goal.

3.2.1 Dynamic link libraries

When attempting to detect misbehaviour of a specific program or its subprocesses a possibility to classify binaries by their general purposes could prove very useful. Most methodologies used to compare executable files focus on their binary structures and attempt to find similarities to existing malware samples [16]. This approach, while very useful in detection of iterations of malicious software, is useless when it comes to creating multidimensional spaces based on their functionality. In this thesis an attempt is made to utilise a novel approach of analysing the processes by their imported Dynamically Linked Libraries. A DLL is a library that contains code and data that can be used by more than one program at the same time. For example, in Windows operating systems, the Comdlg32 DLL performs common dialog box related functions. Each program can use the functionality that is contained in this DLL to implement an Open dialog box. It helps promote code reuse and efficient memory usage [2]. Those code bundles provide specific sets of functionality and are commonly used in all programming languages. Possibly overlapping sets of loaded modules from two given processes can indicate their similar purpose.

Figure 3.1: Example process tree of Microsoft Edge

3.2.2 Subprocess paths

Initial empirical analysis of the impact of the exploit on the behavior of the targeted browser was performed with the use of Windows Performance Analyzer (WPA). Most browsers give a possibility of spawning a new process for example by opening of a downloaded file in adequate software. This makes it harder to detect when it is exploited. However upon closer look on the way that action is performed we can see that proper child process is spawned from the main browser process.

The exploit however generates a new child from the one corresponding to the browser tab in which the exploit was executed.

Patterns like this might be possible to learn and detect. The obtained data can be transformed to create a new feature called "Process Path". It is a string based variable containing names of the consecutive child processes starting from the root of the system process tree leading to the process for which the feature is constructed. All names are divided by any arbitrary separator.

3.3 Anomaly detection algorithms

In the thesis the main anomaly detection algorithm utilised is the One Class Support Vector Machine which is a variation on support vector machine. It at-

Figure 3.2: Process tree of exploited Microsoft Edge

tempts to minimise the radius of the multidimensional hypersphere with the use of Kernel Method [22]. This algorithm is the main anomaly detection utilised in the thesis due to it's ease of usage. It is also known to be efective in high dimensional spaces and when the number of features is greater then the number of samples [8]. The training process does not require significant computational and memory resources when compared to the latest approaches based on artificial neural networks like autoencoders [11]. There are some approaches to training the can be less demanding in example the distributed architecture [21]. Their complexity might however shift the focus from the core idea of the thesis which is to prove that Windows Event Trace can be utilised to detect security anomalies.

The detection process is performed on a per process basis and focuses mainly on the web browser Microsoft Edge.

Chapter 4

Data gathering

This chapter describes the process of gathering data utilised in the experiments and analysed in this thesis. This procedure is necessary due to the lack of commonly available datasets that would fit the needs of work performed.

4.1 Exploit emulation

The data used in the thesis was gathered on a Windows 10 Enterprise Evaluation operating system, version 20H2, build 19042.1052. The Microsoft Edge web browser used to simulate the 0-day exploit attack was artificially halted in the version 84.0.522.52 (64-bit). Automatic updates were interrupted by changing the name of the binary responsible for keeping the software up to date. It is commonly located under "C:\Program Files (x86)\Microsoft\EdgeUpdate\MicrosoftEdgeUpdate.exe". The attack simulated in the data takes advantage of the vulnerability CVE-2021-21224. It targets a type confusion flaw in the V8 JavaScript engine. This allows the attacker to execute arbitrary code inside a sandbox via a specially crafted HTML page [1]. The vulnerability affects the Google Chrome browser prior to the version 90.0.4430.85 as well as Microsoft Edge prior to 90.0.818.41 [3]. Some reports indicate that this vulnerability might have been used by the state backed north korean agents to attack security researchers and gain insight into their work. The exact method of exploitation is not known since the abuse of CVE-2021-21224 does not allow to bypass the builtin Chromium sandbox. There are also reports of Rus-

sian government-backed actors using CVE-2021-1879 to target western european government officials [18]. This method might have been chained with other non-public vulnerabilities in order to perform a successful attack. To simulate such conditions the browser used in testing was run with the `"-no-sandbox"` flag which disables the builtin safeguard.

The sample of the exploit code was obtained from a public GitHub repository [13] and it's code can be found in the listing `"exploit.html"`. It was adjusted to result in the start of the PowerShell.exe process. Execution of this cross-platform task automation solution made up of a command-line shell, a scripting language, and a configuration management framework is usually one of the first steps in the process of gaining persistent access to a given machine. Some actors implement advanced code and logic into the exploit. This is however very uncommon due to the high complexity of such a task.

All the information was gathered in a context of a single user due to restricted available resources and to simplify the task of anomaly detection. Fullfilling the goal of the thesis even in those conditions can be a viable proof of concept which would warrant further research in wider domain.

4.2 Logging

The initial data was gathered by the PerfView.exe tool which is "a free performance-analysis tool that helps isolate CPU and memory-related performance issues. It is a Windows tool, but it also has some support for analyzing data collected on Linux machines. It works for a wide variety of scenarios, but has a number of special features for investigating performance issues in code written for the .NET runtime"[19]. It is capable of tapping into many ETW logging sessions and storing the gathered data into output files. It also has functionality that helps in working with the saved information. Main purpose of PerfView in the thesis was data gathering and preprocessing. The software is open source. It was configured to gather only the "Kernel Base" information. The additional data sources were disabled due to the large quantity of data being generated and not sufficient memory available for the processing. Example PerfView configuration can be found in figure 4.1.

The resulting information is saved to a Microsoft Event Trace Log File (.etl)

Figure 4.1: Example PerfView logging configuration

which can be processed in multiple ways. PerfView has a builtin function of extracting the information gathered about the executed processes and their loaded dll's to Excel executable installed on the system. This can be performed by opening the desired file in the builtin explorer and selecting its "Processes" option. This opens a separate window containing information about processes executed during data gathering and two possible export options - "View Process Data in Excel" and "View Process Modules in Excel". The Excel executable opened by choosing either of the options allows to save the data to multiple easily accessible file formats like .csv, .xml or.xlsx. Loaded data and the export options are presented in figure 4.2.

Resulting from the described process are two files containing correlated information. By default Excel labels those files by including identifying suffixes in their names. The first file is marked by the string "processesSummary" and contains general information about the processes which include following columns:

- Name - Process name - The name of the process, usually identical to the binary file name.

Figure 4.2: PerfView data export

- ID - Process Id - The integer number used by the kernel to uniquely identify an active process [20].
- Parent_ID - Parent Process Id - The Process Id of the process that spawned the correlating one.
- Bitness - Whether the process executable is created in 32 or 64 bit architecture.
- CPUMsec - Ammount of milliseconds in which the process has ocupied the processor.
- AveProcsUsed - Average processor utilisation calculated by dividing the amount of time when process has ocupied the processor by the total process lifespan.
- DurationMSec - The duration of the process life stored in milliseconds.
- StartMSec - The start time of the process stored in milliseconds.
- ExitCode - Integer value returned after the process execution. Commonly known as exit code.
- CommandLine - The command used to spawn the process.

Second output file commonly contains the string "processesModule" in its name. Its contents are the modules (DLL's) loaded by a specific process and information about them. Example output file contains following data columns:

- ProcessName - Name of the process which loaded the corresponding DLL
- ProcessID - Id of the process which loaded the corresponding DLL
- Name - Name of the loaded DLL
- FileVersion - Version of the loaded DLL
- BuildTime - Date when the DLL file was build
- FilePath - The location of the DLL file on the host system

Data gathering was performed on a simulated host usage to acquire inlier data samples required for the algorithm training process. The tasks performed in the process included consumption of online media (eg. youtube.com, netflix.com), office work on cloud based services (eg. Google Docs, Gmail), social media browsing (eg. facebook.com, twitter.com), downloading files and other web browsing. Downloaded files were opened directly from the browser. The data was gathered in the timespan of X hours.

4.3 Preprocessing

Gathered data was initially analysed and processed to fit different machine learning frameworks and to simplify its manual analysis. This operation was complicated by the reuse of process id's in the operating system. In order to identify which of the processes corresponding to the parent id is the true ancestor a additional check is performed based on the time of spawn and the interval in which the possible parent was alive. This algorithm allows the creation of a spawning process path that tracks the ancestors of a given process, usually to one of multiple root programs in the operating system.

Additionally a process of OneHot encoding was performed on the loaded DLL's. The data from the "processSummary" and "processModules" files was correlated by the order in which it was stored. Three of the stored processes never in testing had any corresponding modules - "Registry", "MemCompression" and the process marked with -1 ProcessId.

The final product of the data processing is a dataset containing information about all the executed processes. Each row represents an individual process and following information is provided in the columns:

- ProcName - Process name - The name of the process, usually identical to the binary file name.
- ProcId - Process Id - The integer number used by the kernel to uniquely identify an active process [20].
- ProcPath - String containing sequence of parent processes separated by "/".

-
- ProcPathId - String containing sequence of parent process id's separated by "/".
 - CommandLine - String containing the shell command used to start the process.
 - ParentId - The identifying integer number of the parent process.
 - DLLs - All columns not listed above contain OneHot encoded information about the dynamically linked libraries (DLLs). When a column contains value 1 the process has loaded the dll specified in the column name.

Chapter 5

Experiments

This chapter describes the experiments performed to achieve the purpose of the thesis and the underlying methodology. This includes the utilised tools, information about used datasets, description of the taken actions and presentation as well as analysis of the obtained results.

5.1 Methodology

Experiments performed to achieve the goals of the thesis were executed with the use of the Python 3.8.3rc1 programming language. It was executed via the Jupyter framework which is a is "an open-source web application that allows you to create and share documents that contain live code, equations, visualizations and narrative text. Uses include: data cleaning and transformation, numerical simulation, statistical modeling, data visualization, machine learning, and much more" [6]. Each experiment was performed in a separate Jupyter notebook and obtained results were analysed in the same framework.

Gathered data was also analysed in the Windows Performance Analyzer (WPA) which "is a tool that creates graphs and data tables of Event Tracing for Windows (ETW) events that are recorded by Windows Performance Recorder (WPR) or Xperf. WPA can open any event trace log (ETL) file for analysis" [9]. This software was used to perform initial analysis of the 0-day exploitation of the chromium based browsers and to formulate areas of focus in the gathered data. The tool can be

easily installed on Microsoft Windows operating systems from the Microsoft Store.

5.2 Data sets

5.3 Results

5.3.1 Dynamic link libraries

There are over 1500 different DLL's gathered in the data set created. A single process loads even upto 300 modules. This extremely high dimensionality of the information might be too complex to analyse efficiently. To better understand the gathered information a multiple component analysis (MCA) was performed. This extension of correspondence analysis allows us to analyze the pattern of relationships of multiple categorical dependent variables [10]. This was performed with a python mca 1.0.3 library [7]. The result of this process is a set of points in a low-dimensional map corresponding either to columns or rows of the input data frame. Their distance in the obtained space can be used to classify how strongly they are correlated with each other.

Contents of attached CD

The thesis is accompanied by a CD containing:

- thesis (pdf file),
- source code of applications,
- data sets used in experiments.

List of Figures

3.1	Example process tree of Microsoft Edge	9
3.2	Process tree of exploited Microsoft Edge	10
4.1	Example PerfView logging configuration	15
4.2	PerfView data export	16
